Unreturned Pill Bottles in the 1489 and 1490 Clinical Trials: An Important Measure of Poor Adherence That Is Often Ignored in Pill Count Calculations

Introduction

- Adherence to antiretroviral therapy is important for HIV viral suppression
- Durable viral suppression prevents emergence of drug resistance, improves HIV morbidity and mortality outcomes, and prevents transmission of HIV to others^{1,2}
- There are several methods to assess medication adherence, all with advantages and limitations³:
- Self-reported adherence
- Prescription refill records
- Pill count
- Most HIV clinical trials use pill count to measure participants' adherence
- Limitations include:
- Missing pills are not necessarily pills that were taken
- Adherence pattern cannot be determined (eg, missing drug on consecutive days vs 1 missed dose/wk)
- Adherence by pill count cannot assess causes of poor adherence (illness, vacation, busy, and other)
- Pill count calculations do not include unreturned pill bottles

Figure 1. HIV-1 Viral Loads of 2 Participants With **≥95% Adherence by Pill Count Through Week 144**

- ♦ Virologic suppression with ≥95% adherence by pill count can differ for individuals with unreturned pill bottles (Fig 1)
- Virologic failure without resistance and multiple unreturned pill bottles suggests that poor adherence led to the failure

Objective

To understand the relationship between unreturned pill bottles as a measure of poor adherence and the overall effect on virologic success

Methods

- Treatment-Naïve Adults Study 1489 (NCT02607930) HLA B*5701 negative Negative for chronic HB
- eGFR_{cc} ≥50 mL/min Key inclusion criteria for both: No known resistance to study NRTIs - HIV-1 RNA ≥500 c/mL
- Study 1490 (NCT02607956) Chronic HBV or HCV infection allowed ■ eGFR_{cG} ≥30 mL/min

- treatment (Fig 2)⁴

Adherence (%) = 100 × -

- Fisher exact test
- rank-sum test

Rima K. Acosta, Grace Q. Chen, Hailin Huang, Hui Liu, Kirsten White — Gilead Sciences, Inc., Foster City, CA

Studies 1489 and 1490: Phase 3 studies of B/F/TAF compared with DTG-containing regimens in treatmentnaïve studies; B/F/TAF was noninferior for efficacy to DTG/ABC/3TC and DTG + F/TAF through 144 wk of

– Participants with HIV-1 RNA <50 c/mL by FDA Snapshot at Week 144: 82% for B/F/TAF, 84% for DTG/ABC/3TC, and 84% for DTG + F/TAF

Study drug regimen adherence: adherence (%) of study drug regimen through 144 wk was calculated as:

Total no. of pills taken Total no. of pills prescribed

 Σ No. of pills taken at each dispensing period $= 100 \times \sum$ No. of pills prescribed at each dispensing period

– If any study drug bottle was not returned, all records in that dispensing period for that study drug were excluded from the calculation

Adherence by pill count and FDA Snapshot outcome in Studies 1489 and 1490: median adherence in Studies 1489 and 1490 was ≥95%⁴ Participants with HIV-1 RNA <50 c/mL by FDA Snapshot at Week 144: 88% for those with calculated adherence ≥95% vs 74% with adherence <95%

Virologic events through Week 144: included last ontreatment observation carried forward (LOCF) outcome through Week 144, inclusion in the resistance analysis population, and blip occurrence

- Resistance analysis population included participants with confirmed HIV-1 RNA ≥200 c/mL or ≥200 c/mL at last visit, with no resuppression of HIV-1 RNA to <50 c/mL while on study drug

– Viral blips were defined as HIV-1 RNA ≥50 c/mL preceded and followed by HIV-1 RNA <50 c/mL after achieving confirmed suppression (2 consecutive HIV-1 RNA <50 c/mL)

• Pill bottle return category: defined as all bottles returned or ≥ 1 bottle unreturned (including both study) drug and placebo bottles) and calculated for all participants; association of bottle return category with virologic events through Week 144 was determined by

• Pill bottle return rate: calculated for all participants; association of bottle return rate with virologic events through Week 144 was determined by Wilcoxon

Results

to 81% (Fig 3)

Virologic Failure

(Fig 5)

100 -60 -

In these studies, 60% (764/1266) of participants returned all their pill bottles through Week 144; if 1 visit with \geq 1 unreturned bottle was allowed, this percentage increased

(Fig 4)

Failure to return pill bottles was associated with lower suppression rates at last visit

There was a significant association between different virologic events through 144 wk and fewer pill bottles returned (Fig 6)

Mean bottle return rate was 94% and did not differ by study, treatment arm, or sex

In these HIV-1 treatment-naïve clinical trials of integrase strand transfer inhibitor-based regimens, failure to return pill bottles was associated with lower HIV-1 RNA suppression rates

Although the calculated adherence rates in these studies were relatively high (median \geq 95%), these calculations did not account for unreturned pill bottles

The results show that assessing adherence by both pill count and pill bottle return provides a more complete picture of adherence in HIV-1 clinical trials
